13. ABSTRACT (Maximum 200 words) This report presents numerical data and technical information on the properties of pure silicon and doped silicon materials. Materials comprise a variety of doped silicon materials, having both n-type and p-type conduction. Property coverage includes optical (absorption coefficient and refractive index), thermoradiative (normal spectral reflectance, angular spectral reflectance, normal spectral emittance, and normal spectral transmittance), thermophysical (thermal conductivity, specific heat, thermal expansion, and lattice parameter), and mechanical (elastic constants, stress-strain, yield strength under tensile, compressive, and shear loading, flexural strength, and fracture toughness). Property data are compiled from scientific and technical literature. The compiled data are scrutinized and evaluated through an established set of selection criteria for semiconductor and infrared window materials, and are analyzed for effects due to composition (purity, dopants, carrier concentration), temperature, and wavelength. The electronic version of this report as a computerized PC-based database is also available on a diskette for use on personal computers. This electronic version is for efficient data retrieval, manipulation, and application.

PREFACE

"Optical, Thermoradiative, Thermophysical, and Mechanical Properties of Silicon" is being prepared by the High Temperature Materials Information Analysis Center (HTMIAC). It is published at this time as an *interim* report so as to make the evaluated information available early to users in the DoD and DoD-contractor community and to avoid significant delays. The *interim* report will be improved and expanded and the data contained herein will be further analyzed with the aim of republishing it in final format as an authoritative databook.

Property data for silicon that are available in the literature are widely recognized to be sensitive to variations in material related factors. Many issues that are important in determining property behavior of these materials have been brought forward and widely discussed in the literature. Our objective is to bring them together into a single volume and to document the data and supporting information that bear upon the behavior of silicon, in particular the temperature, wavelength, and composition dependence of its properties.

The present compilation of analyzed property data on silicon is part of a continuing effort for the development, expansion, update, and upgrade of the High Temperature Materials Properties (HTMP) Database, a computerized numerical/ technical database containing numerical data and technical information on materials and properties of interest to high temperature materials technologies. The property data compiled are extensively searched from the worldwide scientific and technical literature, subjected to selection criteria established for material property data capture activities at HTMIAC/CINDAS, and evaluated and analyzed on a property basis in order to clarify discordant data issues and to make effects of affecting variables upon property behavior more readily evident to users of the data.

This interim report is organized with major sections according to property groups. Coverage within each property group is incorporated into subsections dealing with the individual properties of the same property group. Each subsection consists of a sequence of individual data sets and accompanying data plot figures for a series of silicon materials including: intrinsic, various dopants, n-type, and p-type. The property sequence listed under each of the property groups is as follows: for optical properties: absorption coefficient and refractive index; for thermoradiative properties: normal spectral reflectance, angular spectral reflectance, normal spectral emittance, and normal spectral transmittance; for thermophysical properties: thermal conductivity, specific heat, thermal expansion, and lattice parameter; and for mechanical properties: elastic constant, stress-strain, yield strength under tensile, compressive, and shear loading, flexural strength, and fracture toughness.

HTMIAC, a DoD Information Analysis Center, is sponsored and administratively managed and funded by the Defense Technical Information Center (DTIC), ATTN: DTIC-AI, Cameron Station, Alexandria, VA 22304-6145, and is under the IACs program management of Dr. Forrest R. Frank. HTMIAC is operated by the Center for Information and Numerical Data Analysis and Synthesis (CINDAS), Purdue University, West Lafayette, Indiana 47906-1398 under Contract DLA900-93-D-5002. The contract was awarded to Purdue by the Defense Electronics Supply Center (DESC), ATTN: DESC-EACC, Dayton, Ohio 45444-5181 with Ms. Cheryl A. Montoney as the Contracting Officer. HTMIAC is under the technical direction and monitoring of the Contracting Officer's Technical Representative (COTR), Mr. Jerome Persh, Senior Specialist for Materials and Structures, Office of the Director of Defense Research and Engineering (Advanced Technology), ATTN: ODDR&E (AT), The Pentagon, Room 3D1089, Washington, DC 20301-3080 and the Technical Coordinator, Mr. Roger E. Rondeau, Air Force Wright Laboratory, ATTN: WL/MLPJ, Wright-Patterson Air Force Base, Ohio 45433-7702.

HTMIAC serves as the DoD's central source of engineering data and technical information on high temperature materials, especially in the critical technology areas of aerospace structural composites and metals, infrared detector materials, and coatings, and the effects of laser irradiation on these materials. It supports the DoD research, development, test, evaluation, engineering, and acquisition programs as well as defense systems and military hardware in general where scientific and technical information (STI) on high temperature materials technologies is required, and supports the laser effects technology communities with laser-materials interaction data as well as high temperature material property data for laser structural and detector susceptibility, vulnerability, survivability, and hardening assessments and studies in particular. Furthermore, HTMIAC supports the Joint Logistics Commanders/ Joint Directors of Laboratories Technology Panel for Advanced Materials (TPAM), and provides assistance to or receives guidance from other Defense programs and groups as designated by the COTR.

This report is credited to the collective efforts of many HTMIAC and/or CINDAS staff members, who contributed to the technical work and/or the preparation of this report. In addition to the authors listed on the cover, P. D. Desai, J. F. Chaney, V. Ramdas, H. H. Li, J. C. F. Chen, and Carol Dwenger also contributed to this report.

Descriptors-Textual :

After surface treatment, ends were covered with 0.1 microns of copper to make them conductive.

Additional Preparation/Conditioning

Surface Treatment :

Sample ends lapped and polished until optically flat and parallel to within 15 inches of arc.

Specimen Identification

Dimensions (Geometry) :

Length 2.5214 cm

Additional Identifiers :

Length is average of 2.5171, 2.5222, and 2.5248 cm along [100], [110], and [111] orientations, respectively.

Measurement/Evaluation Method

Name/Description :

Ultrasonic Harmonic Generation Technique

Parameters-Textual :

Hard and or elastic constants by harmonic generation.

Excitation of finite amplitude longitudinal ultrasonic wave.

Measurement of fundamental amplitude and the generated second harmonic amplitude used to determine nonlinearity parameters.

Parameters-Codified :

Frequency : 30 MHz

Measured/Evaluated Properties

X : Temperature

K

Y : Elastic Constant, C(111)

Pa

Data Points :

X	Y	Remarks:
4.000e+00	-8.800e+11	St. dev.=+/-16 GPa
7.700e+01	-8.490e+11	St. dev.=+/-14 GPa
2.980e+02	-8.340e+11	St. dev.=+/-11 GPa

Comments on Data

Data taken from table.

Agreement with theory is good.

Figure 112 Elastic Constant, $C_{\langle 111 \rangle}$ of Silicon

MATERIAL: Silicon

HTMIAC/CINDAS 1994

PURDUE UNIVERSITY

PROPERTY: Elastic Constant, C(111)

DATA SET 113

Descriptors-Textual :

After surface treatment, ends were covered with 0.1 microns of copper to make them conductive.

Additional Preparation/Conditioning

Surface Treatment :

Sample ends are lapped and polished until optically flat and parallel to within 15 inches of arc.

Specimen Identification

Dimensions (Geometry) :

Length 2.539 cm

Additional Identifiers :

Length is average of 2.571, 2.522, and 2.5248 cm in [100] [110], and [111] orientations respectively.

Measurement/Evaluation Method

Name/Description :

Ultrasonic Harmonic Generation Technique

Parameters-Textual :

Excitation of a finite amplitude longitudinal ultrasonic wave which propagates along the principal crystallographic direction.

Measurement of fundamental amplitude and the generated second harmonic amplitude used to determine the nonlinearity parameter which contain three linear combinations of 3rd order elastic constants.

Material Preparation

Crystal Growing Method :

Dislocation-free Czochralski crystals grown in various atmospheres including vacuum, argon, N(2)-5% H(2) or purified hydrogen.

Additional Preparation/Conditioning

Surface Treatment :

Samples prepared by grinding with No. 600 SiC grit etching in CP-4 for 3-5 minutes.

Specimen Identification

Dimensions (Geometry) :

Gauge-Section Length	2.5	cm
Width	1.5	mm
Thickness	3.	mm

Additional Identifiers :

orientation along [001]

Measurement/Evaluation Method

Name/Description :

Tensile Loaded Bar Method

Tested with an Instron machine. A thermocouple placed about 2mm away from the specimen measured the temperature.

Parameters-Codified :

Pressure : 1.0e-03 mm Hg

Measurement Laboratory : Raytheon Company, Research Division

Measured/Evaluated Properties

X : Cross-Head Displacement	%
Y : Tensile Stress	Pa
Z1 : Temperature	K
Z2 : Cross-Head Speed	m s ⁻¹

Comments on Data

Data read from Figure 3.

Initial portion essentially linear, at plastic elongation of 0.1-0.2% , stress reaches maximum.

Additional Properties

Other Properties-Textual :

By increasing crystal growth diameter, dislocations from $1e03$ to $1e04/cm[2]$ were incorporated.

Thermal shock was used to obtain dislocations approximately $1e05$ per $cm[2]$.

By bending and flattening, dislocations from $1e06$ to $1e07$ per $cm[2]$ were incorporated.

DATA SET 126

Material Preparation

Crystal Growing Method :

Dislocation-free Czochralski crystals grown in various atmospheres including vacuum, argon, N(2)-5% H(2) or purified hydrogen.

Additional Preparation/Conditioning

Surface Treatment :

Samples prepared by grinding with No. 600 SiC grit and etching in CP-4 for 3-5 minutes.

Specimen Identification

Dimensions (Geometry) :

Gauge-Section Length	2.5	cm
Width	1.5	mm
Thickness	3.	mm

Additional Identifiers :

orientation along [001]

Measurement/Evaluation Method

Name/Description :

Tensile Loaded Bar Method

Tested with an Instron machine. A thermocouple placed about 2mm away from the specimen measured the temperature.

Parameters-Codified :

Pressure : 1.0e-03 mm Hg

Measurement Laboratory : Raytheon Company, Research Division

Measured/Evaluated Properties

Measurement/Evaluation Method

Name/Description :

Compression Loaded Bar Method

Silicon single crystals were deformed in compression at constant strain rates under hydrostatic pressure of 1500 MPa in a solid-confining-medium apparatus.

Parameters-Textual :

The specimen is in contact with a silver jacket. The diffusivity of silver in silicon is so small that during an experiment at the highest temperature (873 K) the penetration of silver is less than one micrometer.

Deformation below 673 K achieved by predeformation at a slower strain rate and temperature above 673 K to eliminate upper yield point. Normal testing then resumed after cooling to desired temperature.

Comments on Data

** predeformation run at 723 K followed by deformation at 573 K
Data was digitized from Figure 1.

Flow stress drops after a maximum and reaches an easy-glide stage after 5 percent strain. A specimen deformed at 673 K fails shortly after the maximum in the stress-strain curve. This gives a rough value of 2800 MPa of the flow-stress under 1500 MPa hydrostatic pressure. Extrapolation of flow-stress values to a failure stress of 2800 MPa showed that it is not likely to be possible to induce deformation below 548 K under these testing conditions.

Comments on Data

Data read from figure

CZ-crystals exhibit yield drop at 1073 K; magnitude of drop decreases progressively with increasing deformation temperature. The drop is absent at 1273 K.

At 1073 K, CZ-crystals exhibit a luders strain. This strain is absent at 1173 K and higher.

Comments on Data

Data read from figure

FZ-crystal exhibit yield drop at 1073 K; magnitude of drop decreases progressively with increasing deformation temperature.

The drop is absent at 1273 K.

The luders strain at 1073 K is not very well defined as was the case for CZ-crystal.

Comments on Data

Data was digitized from Figure 2.

These stress-strain curves of as-grown samples are characterized by high yield stresses, still approximately 40 MPa at 0.9 melting temperature and small hardening rate, becoming negative at 1323 K, strain $> 5.0 \times 10^{-2}$. Samples cut parallel to the radial growth direction are harder than samples cut parallel to the rod axis and have a smaller range of microplasticity.

Figure 134 Compressive Stress of Silicon

MATERIAL: Silicon

HTMIAC/CINDAS 1994

PURDUE UNIVERSITY

PROPERTY: Compressive Stress

DATA SET 135

Vendor/Producer/Fabricator

POLYROD-grade polycrystals obtained from WACKER.

Conditioning History Of Alloys

Heat-Treatment Sequence : Tested in the as-received form

Material Preparation

Film Deposition Method :

Very-high purity polycrystals, POLYROD grade obtained by Vapor deposition (CVD) on a single crystal core and grown to a diameter of about 100 mm. Crystals exhibit a pronounced [110] texture along the radial growth orientation

Specimen Identification

Dimensions (Geometry) :

Length	12.	mm
Width	4.	mm
Thickness	4.	mm

Additional Identifiers :

Sampels stressed along growth axis

Measurement/Evaluation Method

Name/Description :

Compression Loaded Bar Method

High-temperature apparatus mounted to Instron machine.

Tests done under reformed gas.

Parameters-Codified :

Comments on Data

Data was digitized from Figure 3.

A marked softening is observed for both orientations. At

1623 K the flow stress is not modified for samples cut parallel to the rod axis but is reduced by 25 percent for samples cut parallel to the radial growth direction. Hardening rate after annealing is larger--decreased softening at large strains.

Additional Identifiers :

Lateral faces were of {111} and {541} types

Additional Properties

Electrical Properties :

Electrical Resistivity	0.06	Ω cm
Temperature	298.	K

Measurement/Evaluation Method

Name/Description :

Compression Tests of Pre-Strained Crystals

Specimens deformed under argon atmosphere in an Instron
testing machine equipped with a high temperature furnace.

Parameters-Codified :

Pre-Strain Temperature : 1323. K

Pre-Strain Rate, Plastic : 2.e-05 s[-1] (pre-straining)

Experimental Conditioning/Material Degradation

Conditioning/Degradation/Environment : Preconditioning Treatment

Descriptors-Textual :

Specimens pre-strained at 1323 K and 2.e-05 s[-1] strain rate;
it was stopped at a permanent strain of 1.5 pct. and cooled
under load.

Measured/Evaluated Properties

9.130e+02	2.570e+07	2.500e-06

Comments on Data

Data read from figure

Pre-deformation at higher temperatures allows plastic deformation to take place at lower temperatures without brittle fracture. Within the experimental uncertainty, the yield strength of the intrinsic and p-type silicon appear to be in good agreement.

Comments on Data

Data read from figure

Pre-straining at different temperatures and strain rates did not seem to have any appreciable effect on the yield strength. a very strong difference in yield strengths between n-type and intrinsic silicon is observed. The presence of phosphorus in the n-type lowers the yield strength by a ratio of 3 to 4 as compared to the intrinsic type.

Comments on Data

Data read from figures

Single annealing at 1073 K decreases the upper yield strength remarkably at larger annealing time. This is due to the introduction of large plate-like precipitates of SiO(2).

Comments on Data

Data read from figure.

Upper yield strength did not change with annealing time for single-step annealing while decreased with increasing time for double-step annealing.

Comments on Data

Sb-doping in the range 1.0×10^{17} - 1.0×10^{18} cm⁻³ appear to increase the yield point of silicon.

Dopant concentration determined by Hall effect measurement.

Concentrations above 1.0×10^{18} lower the yield point.

Comments on Data

Annealing at 1323 K drastically reduces the yield strength throughout all deformation stages.

Annealing at 1448 and 1593 K does not affect the magnitude of the upper yield of the stress significantly.

Vendor/Producer/Fabricator

KOFU Works of Hitachi Ltd.

Material Preparation

Crystal Growing Method :

Czochralski grown, dislocation free, n-type

Grown with diameter of 76 mm in the [111] direction.

Descriptors-Textual :

Annealed at 1323. K for various times.

Additional Preparation/Conditioning

Surface Treatment :

Surface layers polished and removed to depth more than
250 microns.

Specimen Identification

Orientation With Respect To Material : [123] Direction

Additional Properties

Electrical Properties :

Electrical Resistivity

7-9

Ω cm

Temperature

298

K

Measurement/Evaluation Method

Name/Description :

Shear Response Under Tensile Loading

Test conducted in vacuum using Instron machine mounted to high
temperature apparatus. Resolved shear properties derived from
measured data.

Parameters-Codified :

Pressure : 1.e-05 Torr

Shear Strain, Resolved : 1.1e-04 s⁻¹

Temperature : 1173. K

Annealing Temperature : 1323. K

Comments on Data

Specimens show rapid softening with increase of annealing time.

Figure 152 Shear Stress, Resolved of Silicon: P doped

MATERIAL: Silicon, n-type

HTMIAC/CINDAS 1994
PURDUE UNIVERSITY
DATA SET 153

PROPERTY: Shear Stress, Resolved

Vendor/Producer/Fabricator

POLYROD-grade single crystals obtained from WACKER.

Conditioning History Of Alloys

Heat-Treatment Sequence : Tested in the as-received form

Material Preparation

Crystal Growing Method :

Single crystals obtained by floating-zone technique from
POLYROD n-type silicon, dislocation-free.

Specimen Identification

Dimensions (Geometry) :

Length	14.	mm
Width	4.25	mm
Thickness	4.25	mm

Orientation With Respect To Material : [110] Direction

Additional Identifiers :

Samples stressed along the growth axis.

Additional Properties

Electrical Properties :

Electrical Resistivity	> 5.0	Ω cm
Temperature	298.0	K

Measurement/Evaluation Method

Name/Description :

tests.

Shear Response Under Compressive Loading

High-temperature apparatus mounted to Instron machine.

Tests done under reformed gas.

Shear properties derived from measured data.

Parameters-Codified :

Shear Strain Rate, Resolved : $6.0\text{e-}06 \text{ s}^{-1}$

Comments on Data

Data was digitized from Figure 5.

A stress peak is observed at $T < 1223$ K and a stage of easy glide seems to be present, with a slightly higher hardening rate.

Comments on Data

Data was digitized from Figure 6.

A stress peak is observed at $T < 1223$ K and a stage of easy glide seems to be present, with a slightly higher hardening rate.

Semiconductor Division of Tokyo Shibaura Electric Company Ltd.

Material Preparation

Crystal Growing Method :

Float-zone technique

Crystal grown in a high purity argon gas atmosphere.

Descriptors-Textual :

Dislocation density controlled by deformation at 1173 K and various strains(less than 10 pct shear strain). Specimens then

subjected to thermal annealing for 24 hrs between 1273 and 1473 K.

Specimen Identification

Orientation With Respect To Material : [123] Direction

Additional Properties

Electrical Properties :

Electrical Resistivity

Comments on Data

For specimens showing no yield point phenomenon, the strain at lower yield point is taken as that of intersection of extensions of elastic region and of stress-strain curve. Yield behavior strongly affected by initial density of dislocations.

Material Preparation

Crystal Growing Method :

Float-zone grown, dislocation-free

Additional Preparation/Conditioning

Surface Treatment :

{111} and {541} side faces cut with a diamond saw and
diamond polished (1/4 micron)

Specimen Identification

Dimensions (Geometry) :

Length 14. mm

Thickness 4.25 mm

Width 4.25 mm

Orientation With Respect To Material : [123] Direction

Additional Identifiers :

Specimen oriented to obtain a single slip deformation
along {111} planes and <101> directions

Additional Properties

Electrical Properties :

Electrical Resistivity >5. Ω cm

Temperature 298. K

Measurement/Evaluation Method

Name/Description :

Shear Response Under Compressive Loading

High-temperature compression stage apparatus mounted on an
Instron machine. A continuous flow of forming gas (10 pct. H(2),
90 pct. N(2)) maintained during each test. Curves of resolved
shear stress - strain derived from the recorded data.

Parameters-Codified :

Shear Strain Rate, Resolved : 2.e-05 s[-1]

Comments on Data

Data read from figures.

The curves exhibit the usual shape, with an initial peak stress followed by the three stages characteristic of f.c.c. crystals.

Material Preparation

Crystal Growing Method :

Float-zone grown, dislocation-free

Descriptors-Textual :

crystal pre-strained to extend temperature range towards lower range

Additional Preparation/Conditioning

Surface Treatment :

{111} and {541} side faces cut with a diamond saw and diamond polished (1/4 micron)

Specimen Identification

Dimensions (Geometry) :

Length 14. mm

Thickness 4.25 mm

Width 4.25 mm

Orientation With Respect To Material : [123] Direction

Additional Identifiers :

Specimen oriented to obtain a single slip deformation along {111} planes and <101> directions

Additional Properties

Electrical Properties :

Electrical Resistivity >5. Ω cm

Temperature 298. K

Measurement/Evaluation Method

Name/Description :

Shear Response Under Compressive Loading

High-temperature compression stage apparatus mounted on an Instron machine. A continuous flow of forming gas (10 pct. H(2), 90 pct. N(2)) maintained during each test. Curves of resolved shear stress - strain derived from the recorded data.

Parameters-Codified :

Pre-Strain Rate, Plastic : 7.e-02 pct. (shear)

Shear Strain Rate, Resolved : 2.e-05 s[-1] (pre-straining)

Pre-Strain Temperature : 1323. K

Comments on Data

Best compromise for prestraining was found at $2.e-05 \text{ s}^{-1}$ and 1323 K to create as many mobile dislocations as possible but keep hardening as low as possible.
At 818 K, (lowest temp), silicon can be deformed without cracks.

Comments on Data

Data was digitized from Figure 1.

Lower yield strength curve at 1173 K intersects the 1373 K curve at a strain rate of $0.1\text{e-}03/\text{s}$. Anomalous behavior is due to solubility of boron in Silicon. As diffusion not being negligible at 1173 K, certain amount of boron precipitates and solute level is decreased. Corresponding decrease of lower yield stress shows that impurities in solute state mainly responsible for observed effects and few precipitated particles do not have much influence on yield point.

Comments on Data

Data was digitized from Figure 2.

Lower yielded strength at 1173 K curve intersects the 1373 K curve at strain rate of $0.1e-03/s$. Anomalous behavior due to solubility of boron in Silicon. Diffusion not being negligible at 1173 K, certain amount of boron precipitates and solute level decreased. Corresponding decrease of lower yield stress shows that impurities in solute state mainly responsible for observed effects and few precipitated particles do not have much influence on yield strength

Measurement/Evaluation Method

Name/Description :

Compression Loaded Bar Method

Silicon single crystals were deformed in compression at constant strain rates under hydrostatic pressure of 1500 MPa in a solid-confining-medium apparatus.

Parameters-Textual :

The specimen is in contact with a silver jacket. The diffusivity of silver in silicon is so small that during an experiment at the highest temperature (873 K) the penetration of silver is less than one micrometer.

Deformation below 673 K achieved by predeformation at a slower strain rate and temperature above 673 K to eliminate upper yield point. Normal testing then resumed after cooling to desired temperature.

8.820e+02	5.500e+07	5.000e-05

Comments on Data

Data was digitized from Figure 2.

A graph of log yield strength against T suggests a change of slope occurring at 873-923 K. This is taken as the transition temperature. This change of slope could also denote that different thermally activated mechanisms govern the deformation rate at large stresses and low temperatures on one hand and at low stresses and high temperatures on the other.

Measurement uncertainty estimated to be +/- 50 MPa, mostly due to friction.

1.200e-02	1.160e+07	1.373e+03
2.400e-02	1.440e+07	1.373e+03

Comments on Data

Lower yield strength of the heavily doped crystals showed marked deviations from that of pure and low doped crystals especially at low strain rates. Behavior interpreted as solid solution hardening due to electrostatic interaction between dislocations and solute atoms.

1.719e+05	6.800e+06	1.323e+03	1.173e+03	1.100e-04

Comments on Data

Yield strength decreased drastically with annealing time in the range of 0 to 10 hours; longer annealing time did not significantly reduce yield strength.

1.527e+03	1.100e+06	2.000e-04

Comments on Data

At the lower strain rate, the temperature dependence consists of three stages. The low-temperature range in which the yield strength decreases rapidly with increasing temperature followed from about 1170 - 1320 K by a plateau where it remains constant or even slightly increases with temperature. At higher temperatures the flow stress extrapolated from stage I of easy glide decreases again. At higher strain rate the plateau no longer appears.

Comments on Data

Lower yield strength of pre-strained crystals did not exhibit the same plateau observed for the as-received crystals at all temperatures.

Pre-straining conditions (2.e-05 s⁻¹ at 1323 K) chosen to create as many mobile dislocations as possible but at the same time keep hardening as low as possible.

Comments on Data

Dislocation density determined by etch-pit technique.

Lower yield strength, unlike upper yield, does not seem to be affected by dislocation density.

MATERIAL: Silicon, p-type

HTMIAC/CINDAS 1994

PURDUE UNIVERSITY

PROPERTY: Shear Strength, Resolved, Lower Yield

DATA SET 176

Material Preparation

Crystal Growing Method :

Float-zone, p-type, dislocation free

Additional Preparation/Conditioning

Surface Treatment :

The surfaces were lapped with diamond paste and chemically polished

Specimen Identification

Dimensions (Geometry) :

Length 15. mm

Width 3.4 mm

Thickness 3.4 mm

Orientation With Respect To Material : [123] Direction

Additional Properties

Electrical Properties :

Electrical Resistivity 200-1200 Ω cm

Temperature 298. K

Measurement/Evaluation Method

Name/Description :

Shear Response Under Compressive Loading

High-temperature apparatus mounted to Instron machine. Tests carried under an atmosphere of forming gas (92 pct N₂, 8 pct H₂).

Resolved shear properties derived from measured stress-strain curves.

Measured/Evaluated Properties

X : Temperature

K

Y : Shear Strength, Resolved, Lower Yield

5.200e-03	2.740e+07	1.373e+03
1.200e-02	4.030e+07	1.373e+03

Comments on Data

Data was digitized from Figure 1.

At high strain rates the slope of curves is the same for pure and doped Silicon. The stress exponent of dislocation velocity remains unchanged by doping in this region. At low strain rates the yield point, especially lower yield, is independent of strain rate.

Comments on Data

Carbon results in increase in mechanical strength of silicon crystals if it coexists with oxygen concentrations higher than 5.0×10^{17} atoms/cm³. Upper yield stress increases monotonically with increase in carbon concentration.

-----------	-----------	-----------

Comments on Data

The upper yield strength increases with a decrease in dislocation density. At 1073 K effect is more profound as compared to 1173 K Results show that carbon atoms dissolved in a silicon crystal have little effect in locking dislocations by themselves without the presence of oxygen atoms.

8.400e+23	2.000e+07	1.173e+03	9.000e+22

Comments on Data

Carbon content has no effect on dislocation-free crystal.

Upper yield strength increases distinctly by presence of carbon if crystal contains oxygen at concentration above 5.0×10^{17} atoms/cm³.

Carbon content has almost no influence on upper yield strength when oxygen content is below 4.0×10^{17} atoms/cm³.

4.900e-03	2.100e+07	
1.300e-02	2.780e+07	

Comments on Data

Upper yield strength of the heavily doped crystals showed marked deviations from that of pure and low doped crystals over the range of stain rates studied. Behavior interpreted as solid solution hardening due to electrostatic interaction between dislocations and solute atoms.

1.274e+03	4.800e+06	2.000e-04
1.329e+03	4.000e+06	2.000e-04

Comments on Data

At the lower strain rate, the temperature dependence consists of three stages. The low-temperature range in which the yield strength decreases rapidly with increasing temperature followed from about 1170 - 1320 K by a plateau where it remains constant or even slightly increases with temperature. At higher temperatures the flow stress extrapolated from stage I of easy glide decreases again. At higher strain rate the plateau no longer appears.

Comments on Data

Dislocation density determined by etch-pit counting technique.

Yield strength decreases with increasing dislocation density.

Vendor/Producer/Fabricator

Semiconductor Division of Tokyo Shibaura Electric Company Ltd.

Material Preparation

Crystal Growing Method :

Float-zone technique

Crystal grown in a high purity argon gas atmosphere.

Descriptors-Textual :

Dislocation density controlled by deformation at 1173 K and various strains(less than 10 pct shear strain). Specimens then subjected to thermal annealing for 24 hrs between 1273 and 1473 K.

Specimen Identification

Orientation With Respect To Material : [123] Direction

Additional Properties

Electrical Properties :

Electrical Resistivity	460.	Ω cm
------------------------	------	-------------

Temperature	298.	K
-------------	------	---

Other Properties-Numerical :

Dislocation Density	2.0e04	cm ⁻²
---------------------	--------	------------------

Measurement/Evaluation Method

Name/Description :

Shear Response Under Tensile Loading

Parameters-Textual :

Tensile tests using an Instron-Type machine. All specimens showed homogeneous deformation along gauge length. No deformation by means of the propagation of luders bands occurred.

Parameters-Codified :

Pressure : 1.3e-02 Pa

Experimental Conditioning/Material Degradation

Conditioning/Degradation/Environment : Vacuum Environment

Comments on Data

Data read from Figure 5.

Yield properties dominated by surface imperfections; dislocations can be nucleated which might account for the spread in data.

No significant effect of dissolved oxygen is seen on yield strength of as-grown crystals.

Comments on Data

Data read from Figure 6.

**Value given as <0.5, annealed for 36 hrs. at 1323 K.

***Annealed for 16 hrs. at 1323 K.

Specimens contained an initial dissolved oxygen concentrations of 29.5 +/- 0.5 ppma.

Results show that carbon plays an indirect role in reducing the yield strength.

Material Preparation

Crystal Growing Method :

Dendritic web silicon ribbons grown along a {211} crystal orientation with {111} surfaces.

Two thin single crystal sheets separated by odd number of twin planes.

Additional Preparation/Conditioning

Surface Treatment :

Laser cut along length of ribbon, along [211] direction.

After laser cut, mechanically polished with emery paper and diamond paste.

chemically polished using planar etch.

Specimen Identification

Dimensions (Geometry) :

Length 64.77 mm

Width 21.60 mm

Gauge-Section Thickness 25.40 mm

Gauge-Section Width 12.80 mm

Additional Identifiers :

Multiple slip orientation along (111)[101] and (111)[110] systems

Additional Properties

Other Properties-Numerical :

Dislocation Density 1.e+06 cm⁻²

Temperature 298. K

Measurement/Evaluation Method

Name/Description :

Shear Response Under Tensile Loading

Tensile axis of specimen is along the [211] direction, the ribbon growth direction.

Constant extension rates in a high temperature testing chamber mounted on a servohydraulic MTS machine.

Test performed in ultra high purity argon atmosphere.

Heating by infrared elliptical furnace.

Parameters-Textual :

All specimens strained to 5 percent elongation.

Parameters-Codified :

Strain Rate : 1.e-05 to 5.e-04 [s-1]

Elongation : 5 percent

2.950e+02	4.000e+08	Data Scatter = +/- 50 MPa (approx.)

Comments on Data

Precursor cracks healed by annealing at from 900 C to 1100 C for an appropriate time.

The healing mechanism is the growth of a bonding layer of SiO(2), which proceeds as a reaction-rate-limited growth process.

Figure 209 Flexural Strength of Silicon: B doped

MATERIAL: Silicon: B doped

HTMIAC/CINDAS 1994
PURDUE UNIVERSITY
DATA SET 210

PROPERTY: Flexural Strength

Vendor/Producer/Fabricator

Mitsubishi Electric Corp.

Material Preparation

Crystal Growing Method :

Czochralski-grown crystals

Descriptors-Textual :

Chemically polished and then annealed at 1073 K for 100 hrs.

Specimen Identification

Dimensions (Geometry) :

Length 32. mm

Width 5.0 mm

Thickness 0.53 mm

Orientation With Respect To Material : [110] Direction

Additional Properties

Electrical Properties :

Electrical Resistivity 15-25 Ω cm

Temperature 298. K

Other Properties-Textual :

Etch pit density: approx. 8.0×10^9 cm⁻³

SiO₂ precipitate size: approx. 4200 Angstroms.

Measurement/Evaluation Method

Name/Description :

Four-Point Bend Test

Parameters-Textual :

Four-point loading device made of quartz and the distances between inner and outer knife-edges are 8 and 24 mm, respectively.

The device was attached to an Instron machine.

Parameters-Codified :

Strain Rate : 1.5×10^{-6} s⁻¹

Measured/Evaluated Properties

X : Temperature K

Y : Flexural Strength Pa

Data Points :

X	Y
2.990e+02	1.306e+08

7.330e+02	2.392e+08
7.800e+02	4.199e+08

Comments on Data

Data was digitized from figure 2

Fracture strength at room temperature does not change with heat treatments if surface-denuded zones (DZ) present.

Platelike SiO₂ precipitates of about 10.e10cm⁻³ are observed by TEM and etch-pit method, but no punched-out dislocation loops exist. Annealed CZ wafers become ductile at T above 793 K.

6.584e+04	2.100e+09	S.D.=0.56 GPa,O + E + PO

Comments on Data

Surface-treatment(oxidation) test series are identified by:

CP = Chemical Polish

O = Oxidation

PO = Partial Oxidation

E = Etched to remove oxide

Number of specimens was eight per test series.

An oxide layer 0.70 micron thickness on the compression side is observed to increase the fracture strength.

Material Preparation

Crystal Growing Method :

Float-Zoned

Additional Preparation/Conditioning

Surface Treatment :

As-received wafers had one mirror finish surface (tension surface) and one deep etched surface (compression surface).

The deep etched surface was heavily etched with CP4 (HF:HNO₃:glacial acetic acid = 3:5:3).

Specimen Identification

Number/Name : Float-Zone p-type silicon, implantation and RTA effect

Orientation With Respect To Material : (100) Plane

Additional Properties

Electrical Properties :

Electrical Resistivity

>30

Ω cm

Temperature

295

K

Measurement/Evaluation Method

Name/Description :

Ball-and-Ring Flexure Test for Wafers.

Circular aluminum platform had 5 mm diameter hole with a beveled edge to provide concentric support.

Load was applied by a 5 mm ball attached to an Instron machine.

Crosshead speed was 100 micron/min.

Fracture load was converted to flexure strength (tensile surface stress at fracture) using elastic bending theory.

Experimental Conditioning/Material Degradation

Conditioning/Degradation/Environment : Ion Implantation

Descriptors-Numerical :

Annealing Temperature

1250

$^{\circ}$ C

Descriptors-Textual :

Ion-implantation parameters: Ge(+) with 1.0e+15 cm⁻² dosage.

Ion-implantation parameters: B(+) with 1.0e+15 cm⁻²

Ion-implantation parameters: B(+) with 1.0e+16 cm⁻²

Ion-implantation parameters: Sb(+) with 3.76e+14 cm⁻²

Ion-implantation parameters: Sb(+) with 3.76e+15 cm⁻²

Implantation was followed by rapid thermal anneal(RTA)

Lot 1

Specimen Identification

Number/Name : Lot 1, Series A and B specimens.

Additional Identifiers :

Wafer surface orientation was either (100) or (111).

Measurement/Evaluation Method

Name/Description :

Ball-and-Ring Flexure Test for Wafers

Parameters-Textual :

Circular aluminum platform had a 5 mm diameter hole with a slightly rounded edge to provide concentric support.

Load was transmitted to wafer by means of a spherical ball (ball diameter either 1.2 or 5.0 mm). Load was increased incrementally to fracture.

Flexure strength was calculated as the stress at fracture in the tensile surface using elastic bending theory.

Measured/Evaluated Properties

X : Temperature

K

Y : Flexural Strength

Pa

Data Points :

X	Y	Remarks:
2.950e+02	3.000e+09	S.D.=0.87 GPa,(100) Surface,1.2 mm Ball Radius

2.950e+02 3.100e+09 S.D.=1.4 GPa, (100) Surface, 5.0 mm Ball Radius

2.950e+02 2.100e+09 S.D.=0.8 GPa, (111) Surface, 1.2 mm Ball Radius

2.950e+02 2.800e+09 Standard Deviation Overall=1.2 GPa

Comments on Data

Ball diameter had no measurable effect on fracture strength.

Fracture strength for (100) surface is about 50 percent higher than for (111) surface, but the statistical significance is uncertain.

Presence of edge flaws was inconsequential for this test method.

1.050e-04	2.750e+08	5.000e-01	2.950e+02

Comments on Data

The test limit was 250 - 300 MPa, so that the highest strengths were not determined.

The tabulations were read from Figures 10 and 11 which incurred data point reading errors of +/- 0.4 micron etch depth and +/- 2 MPa fracture strength.

The data indicate that grinding damage can be removed by etching about 15 micron of material, while lapping damage is much more difficult to remove.

Microscopy (SEM) of low-stress fractured surfaces indicated that cracking was initiated at flaws that were either etch pits or scratches, typically 10 micron long and 1 micron wide,

that occurred after etching.

Comments on Data

Data was digitized from figure 2

Yield strength of wafers at 973 K are remarkably lowered by heat treatment. Platelike SiO₂ precipitates of about 10.e10cm⁻³ are observed by TEM and etch-pit method, but no punched-out dislocation loops exist. Annealed CZ wafers become ductile at T above 793 K.

Material Preparation

Crystal Growing Method :

Floating-Zone (FZ)

Additional Preparation/Conditioning

Conditioning/Preparation : Precursor Crack Generation

Descriptors-Textual :

Specimens were chemically polished to remove surface damage prior to indenting (CH(3)COOH:HNO(3):HF (1:10:1))

Precursor crack produced by Knoop diamond indenter at center of tensile surface and in (110) plane such that crack was oriented perpendicular to tensile stress. Indentation load varied from 50 to 500g.

Pre-cracked specimens were annealed in a quartz furnace at 700 C under vacuum of 2.6×10^{-4} Pa.

Material Microstructure

Dislocation-free 100 mm diameter (001) wafers

Interstitial oxygen (infra-red absorption): $1.0 \times 10^{16} \text{ cm}^{-3}$ in FZ crystals.

Substitutional carbon content was below instrumental detection limit

Specimen Identification

Dimensions (Geometry) :

Length	32	mm
Width	4	mm
Thickness	0.5	mm

Orientation With Respect To Material : [110] Direction

Additional Properties

Electrical Properties :

Electrical Resistivity	17-23	$\Omega \text{ cm}$
Temperature	295	K

Measurement/Evaluation Method

Name/Description :

Four-Point Bend Test on Pre-Cracked Specimens

Instron machine (Model TTCM-L) fixture has stainless steel sample supports separated by 25mm (outer) and 10mm (inner).

The fracture stress on the outermost (tensile) surface was computed by simple elastic beam theory.

Parameters-Codified :

Cross-Head Speed : 0.02mm min⁻¹

Measured/Evaluated Properties

X : Temperature

Y : Fracture Toughness, Plane-Strain K_{Ic}

K
Pa m^{1/2}

Data Points :

X	Y	Remarks:
2.950e+02	9.100e+05	S.D. = 0.09 MPa m ^{1/2} , (110) Crack Plane

Comments on Data

Approximately 30 specimens having varying pre-cracked lengths were measured and averaged together.

SEM profiles of the fracture surface indicate a semi-elliptical precursor crack and no stable crack growth.

Vacuum annealing evidently releases residual stresses around the precursor crack which would otherwise act as a driving force for crack extension.

Alternatively, annealing in air or oxygen was found to heal precursor cracks and increase fracture strength.

No appreciable difference between CZ and FZ material was observed.

1.210e+03	1.000e+06	8.333e-06	

Comments on Data

Ductile-to-brittle transition is between 1074 and 1078 K for 50 micron/min cross-head speed.
The extrapolations were made from a few data points just below the ductile-to-brittle transition for each cross-head speed.
The fracture toughness was found to be essentially temperature and rate independent.

Measurement/Evaluation Method

Name/Description :

Indentation Fracture Method For Fracture Toughness

Under ambient conditions, the load dependence of both radial and diagonal cracks was measured. Crack lengths were measured along the surface around the indentations.

The expected crack planes include (110) planes normal to the (111) surface. Their traces perpendicular to the sample surface lie along $\langle 121 \rangle$.

Existing theory of radial crack growth due to indentation stress fields was applied. Literature values of tensile modulus and (Vickers) hardness were used to calculate fracture toughness.

Parameters-Textual :

Instrom machine was employed with cross-head speed of 0.127 cm/min.

Measured/Evaluated Properties

X : Temperature
Y : Surface Energy for Cleavage

K
J m⁻²

Data Points :

X	Y	Remarks:
2.930e+02	1.900e+00	Stand. Dev. = 0.20, (110) Crack Surfaces

Comments on Data

Fracture strength versus precursor-crack length for six specimens was averaged to compute the surface cleavage energy for (110) crack surfaces.

Evidence indicated that the Griffith criterion for stress field at the precursor-crack tip was satisfied.

Monsanto Company, St. Louis, Mo.

Additional Preparation/Conditioning

Conditioning/Preparation : Precursor Crack Generation

Descriptors-Textual :

As-cut specimens were lapped with 600 grit silicon carbide and subsequently etched.

Precursor cracks were produced by scribing lines on the flat faces of the specimens.

Precursor cracks from $L/3$ to $2L/3$ in length (L = specimen length) resulted in compliance being proportional to crack length.

Specimen Identification

Number/Name : Double-Torsion Specimen

Dimensions (Geometry) :

Length	25.4	mm
Width	6.4	mm
Thickness	0.38	mm

Additional Identifiers :

Specimen flat faces were {100} planes

Precursor crack planes were {110} planes

Additional Properties

Electrical Properties :

Electrical Resistivity	173+/-10	Ω m
Temperature	295	K

Measurement/Evaluation Method

Name/Description :

Double-Torsion Method

An Instron machine was fitted with a compression cage, a double torsion jig and a CM load cell.

Parameters-Textual :

A cross-head speed of 0.127 mm s⁻¹ was used.

Crack length was measured by optical microscopy on cleaved surfaces and the orientation was determined by the Laue back reflection method.

The theoretical model took elastic anisotropy into account.

Measured/Evaluated Properties

X : Temperature
Y : Surface Energy for Cleavage

K
J m⁻²

Data Points :

X	Y
2.950e+02	1.810e+00

Comments on Data

Fracture occurred in Mode I and was of type (110)[110].

The critical load value was 0.650 kg.

Critical stress intensity was 0.74 MN m^[-3/2].

Critical energy release rate was 3.62 J m^[-2].

Additional Preparation/Conditioning

Conditioning/Preparation : Precursor Crack Generation

Descriptors-Textual :

Polished and thinned slices were carefully cracked at one edge while rigidly clamping the slice.

Measurement specimen was cut from such a precracked slice.

Material Microstructure

Single-crystalline material

Measurement/Evaluation Method

Name/Description :

Double Cantilever Beam Using a Pre-Cracked Specimen

Tungsten-wire hooks were attached to each side of crack to apply force while the specimen was immersed into liquid nitrogen.

Parameters-Textual :

Loading was accomplished by adding links of a chain (1.7g/link) to the specimen.

Crack length was measured along the fracture surfaces using a traveling microscope.

Existing theory for double cantilever beams was used to analyse the data.

7.715e+01 1.230e+00 Average for 15 specimens, (111) Crack Planes

Comments on Data

Since dissipative factors tended to increase the surface cleavage energy, any high values were excluded from the tabulations.

The crack surfaces were (111) planes in each case.

Material Preparation

Crystal Growing Method :

Floating-zone

Additional Preparation/Conditioning

Conditioning/Preparation : Precursor Crack Generation

Descriptors-Textual :

Specimens were cut, slotted at one end, had holes bored for attachments, and chemically polished with HF + HNO₃.

Precursor crack was initiated by abrading the base of the slot.

Initial crack was started by using a knife blade jig immersed in liquid nitrogen.

Material Microstructure

Single crystals of semiconductor grade silicon

Specimen Identification

Number/Name : Specimen numbers S-10 and S-4.

Dimensions (Geometry) :

Length	8.5	mm
Width	2.20	mm
Thickness	2.84	mm
Length	10.1	mm
Width	3.10	mm
Thickness	1.93	mm

Additional Identifiers :

Specimen sides (one set) were {111} planes

Specimen length was along <112>.

Measurement/Evaluation Method

Name/Description :

Double Centilever Beam Using a Pre-Cracked Specimen.

Parameters-Textual :

A specially designed yoke attached to the specimen by pivot bearings was used to transmit force to the specimen.

An Instron testing machine was used with load applied at a rate of 8 gram/sec.

Critical loads for crack propagation correspond to loads

for which the crack length suddenly increased by some amount.
Crack length was measured by microscopic examination of the
cleaved surfaces.

Surface cleavage energy was obtained from a theoretical
modeling of critical crack growth.
